Sean Tubbs (smt2436), Erik Lopez(el8779)

To compile the source code into a JAR executable, we used Eclipse. We created a project that included all .java files that are in our .zip plus a Main.java with a static void main method used to test our methods (Main.java not included in the .zip – presumably you, the grader, have a similar file you will use to grade our project with). When creating the JAR, it is required to specify which file has the static void main method (in our case, we chose Main.java). To run, the following can be typed on Linux command line:

java –jar <relative path to jar executable file>

ex: java –jar hw1.jar
